The model, the environment, and the decision

A checked notation contract and a strict public-information boundary

Specify and compile

GNN declares fleet labels, observations, priors, preferences, and time.
The upstream parser and strict adapter bind the supported backend.

ENVIRONMENT

Hidden selected fleet

Generates deterministic
hit or miss at the chosen cell.
Its layout stays private.

Execute one shot

An unvisited coordinate is chosen.
The next observation starts
another update.

ASSISTANT

Joint posterior

Given public cell and hit/miss,
update joint fleet log weights.
Cells remain correlated.

Compare legal actions

Preference cost − β × information
Softmax with precision and habits

Scope of this implementation

Exact Bayesian updates within a sampled, biased catalog; one-step action scoring.
Assumed sensor noise changes beliefs, not the truthful game environment.
No arbitrary GNN execution, unrestricted fleet-space inference, or learning.

Generalized Notation Notation is a model specification, not a graph neural network.
